

LangGraph: Building Cyclic Agent Workflows

Introducing LangGraph LangGraph is an extension of LangChain designed to build stateful, multi-actor applications with cyclic control flows. Unlike standard linear chains, LangGraph allows modeling loops and complex graphs, which are common in advanced agent architectures.

Key Architecture Components

- **State:** A shared schema or dictionary representing the current context, updated dynamically by graph execution nodes.
- **Nodes:** Functions or agent steps that receive the current state, perform operations, and return updates to the state.
- **Edges:** Connections between nodes. Conditional edges determine which node to visit next based on the state output.

Human-in-the-Loop Operations LangGraph features native support for interrupts, enabling human approval or manual input correction before proceeding past specific state transitions.
